Kubernetes is not used to create the application containers; it actually needs a container platform to run, Docker being the most popular one. Kubernetes integrates with a large toolset built for and around containers and uses it in its own operations. Containers created with Docker or any of its alternatives can be managed, scaled and moved by Kubernetes, which also ensures failover management and health maintenance of the system.

Docker containers are similar to virtual machines, but don't create an entire virtual operating system. Instead, Docker enables the app to use the same Linux kernel as the system that it's running on. This allows the app package to only require parts not already on the host computer, reducing the package size and improving performance. Continuous availability, using Docker containers with tools like Kubernetes, is another reason for

Kubernetes isn't the only container management tool around. Docker also has its own native container management tool called Docker Swarm. It lets you deploy containers as Swarms that you can interact with as a single unit, with all the container management taken care of. After pulling the Oracle database schema application from the Github site, the developer protects the updated state of the database code and data by using Kubernetes to take a snapshot persistent volume container (PVC) of the database. After a round of destructive testing, the developer then restores the database to the preserved state by using Kubernetes and snapshot PVC.
